Per disease: where does its best own-organ cell type rank?

One dot per disease with a single primary organ. Black tick = the organ's chance rank: the MEDIAN rank of that organ's best cell type across all diseases that do not have it as an organ.
Blue = this disease ranks its own organ better (further left) than that median. Ring = p < 0.05 for that disease alone: p is the share of the other diseases that rank the organ at least as high.
No single disease passes a multiple-testing correction (see text). Organ q = organ-level test: do this organ's diseases (near-duplicates counted once) rank it better than random groups
of other diseases do? Benjamini-Hochberg across organs; bold = q < 0.05. Organs sorted by median distance from chance.
