Organ score per disease, with the organ-level effect

Dots: one per disease with that primary organ. Organ score = mean disease-specific z over ALL the organ's cell types (minus the disease's mean), expressed in SDs above the diseases that do not have that organ. Blue = significant after hierarchical FDR (organs first, then diseases within selected organs), with p calibrated by label shuffles. Diamond and bar: organ effect from a mixed model (near-duplicate diseases share a group effect, small organs are pulled toward the average), approximate 95% interval, not corrected for the number of organs. Filled diamond = organ selected by the FDR step.
