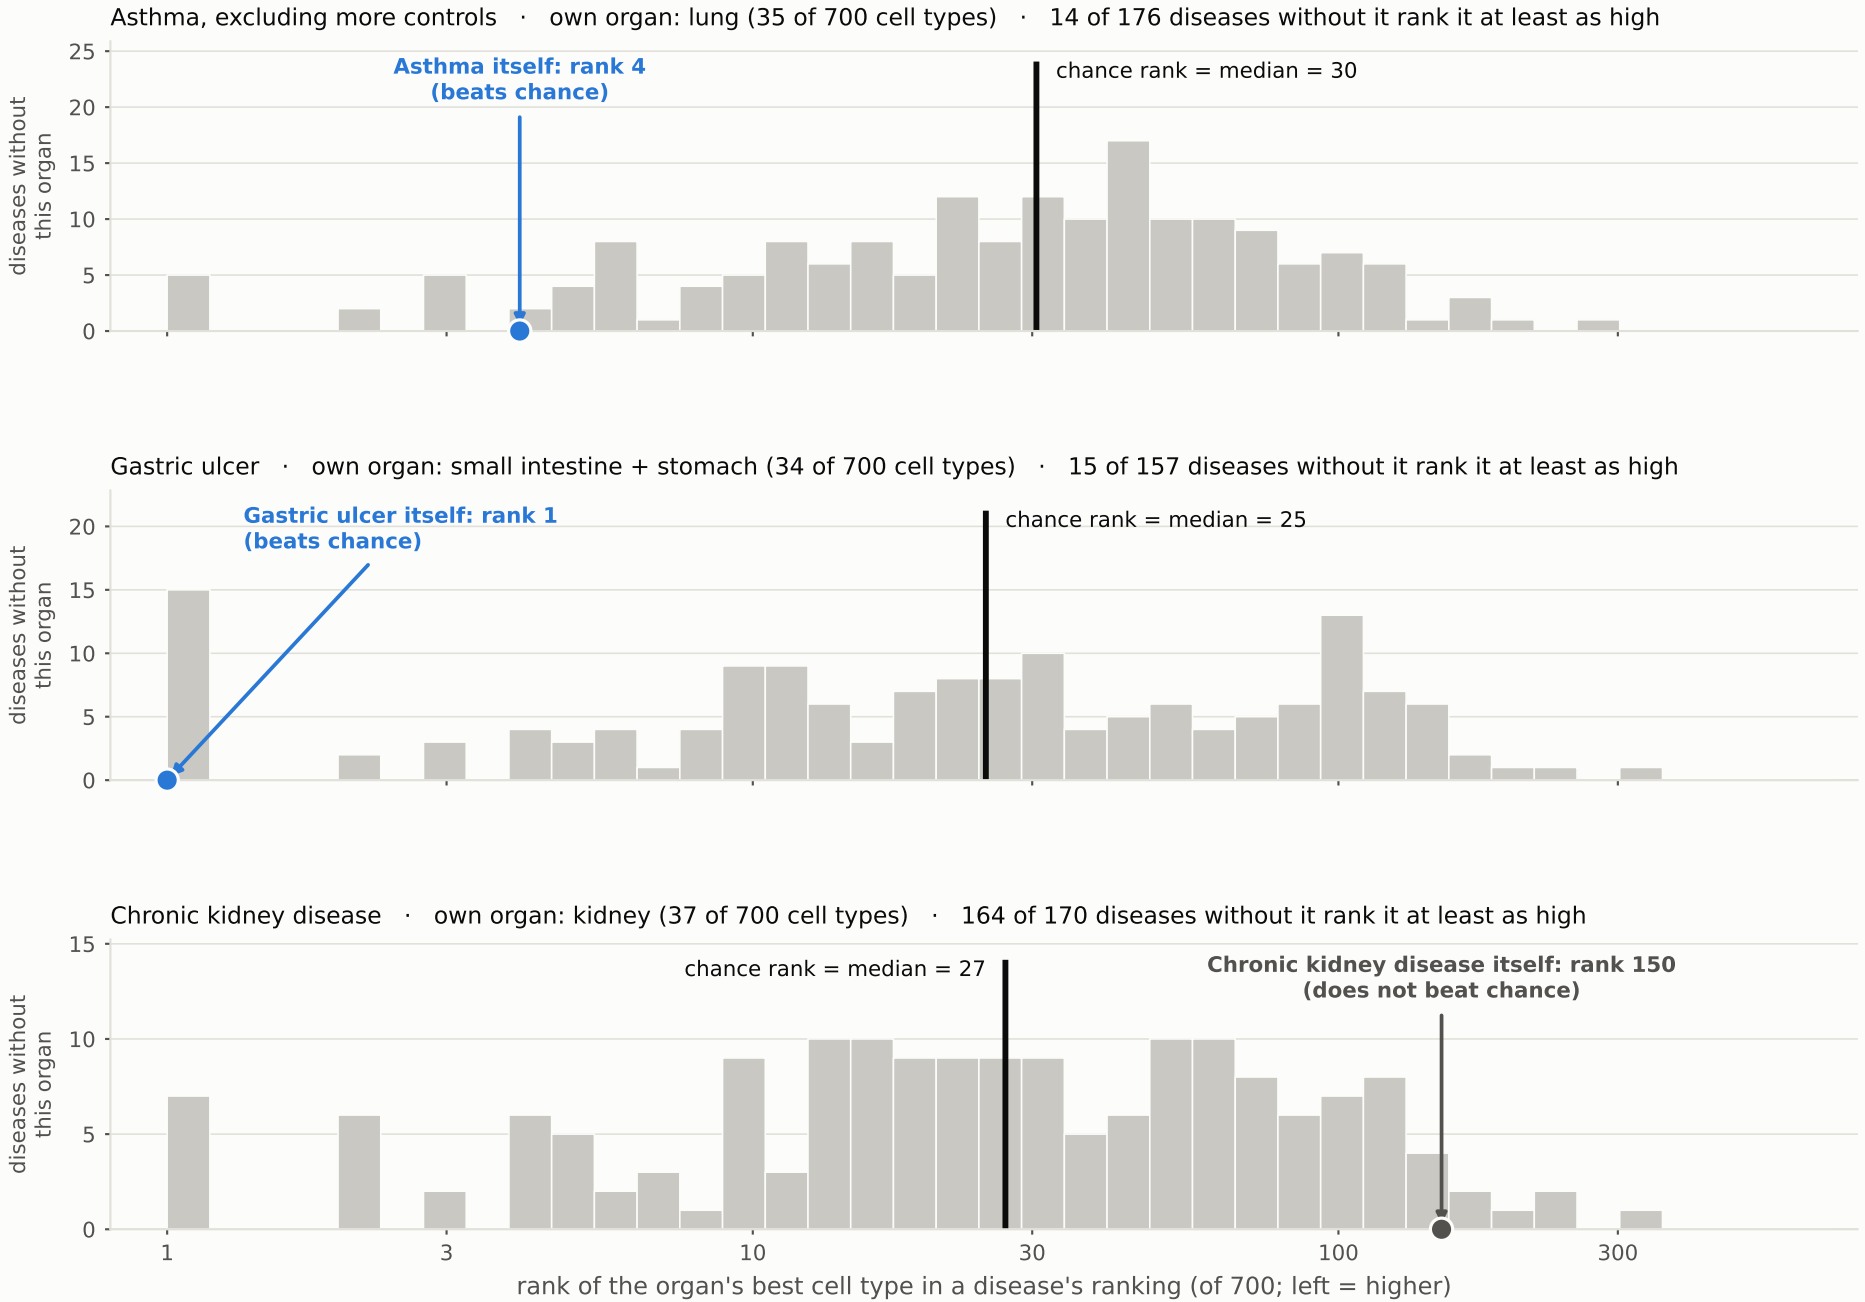
How the chance rank (the black tick in Figures 3 and 5) is computed


Gray bars: take every disease that does NOT have this organ among its own organs, and find where the organ's best cell type lands in that disease's ranking.
Black line: the median of those positions = the organ's chance rank. The disease beats chance if its own rank (dot) is left of the black line.
Because it is a median, a disease whose ranking says nothing about its organ would land left of it about half the time: that is the '~50% expected'.
