Per disease and organ: where does that organ's best cell type rank?

One dot per (disease, organ in its own set): filled = primary organ (upper dots), open ring = secondary organ (lower dots). A disease with several organs has several dots.
Black tick = the organ's chance rank: the MEDIAN rank of that organ's best cell type across all diseases that do not have it as an organ (same definition as Figure 3).
Blue = this disease ranks the organ better (further left) than that median; a disease with no organ information would land left of the tick about half the time.
Row label: organ (primary pairs + secondary pairs). Any own organ beating chance = any blue dot of the disease. Organs sorted by the primary pairs' distance from chance.
